Belkasoft Live RAM Capture

The possibilities of Belkasoft Live RAM Capture include capturing protected memory regions and creating full physical memory dumps that may contain private browsing data, chat sessions, decrypted content, credentials, and malware artifacts. The tool is lightweight and easy to run while it complies with forensic requirements for capturing memory. This tool can be easily deployed in law-enforcement environments because you can use it in many Windows versions and it is free.

A challenge for this RAM Capturing tool is that it is built for windows. Linux and macOS hosts are increasingly common and you must use other memory acquisition tools for those hosts. Another challenge is that these dumps have very large memory sizes which touch on device storage capacity. For example, my memory dump file was 18.1 GB. Lastly, different tools will be required to thoroughly examine raw memory dump files.

WinHex

You may be able to use WinHex to examine raw memory dumps at a low level such as hex view, sectors, and structures, which is useful for retrieving digital remnants or evidence from devices. This includes recovering deleted or damaged data which can provide information about file systems and metadata. WinHex is also used for imaging and integrity verification and can be used to tell if the dump was altered during transfer or storage.

Compared to dedicated forensic applications, WinHex is a very generic hex and disk editor which can make RAM dump analysis more time-consuming than needed. WinHex also does not have many logical search functions upon forensic images where the tool can miss important digital evidence. Lastly, WinHex allows for direct editing which you must avoid to not accidentally modify images that serve as evidence.
